

The Upper West Side vs Upper Manhattan: A Tale told by Traffic

For my submission of The Explorer Transportation Data Science Project, I chose to examine the differences in traffic patterns between the Upper West Side neighborhood of New York and Upper Manhattan.

An analysis of crash causes shows little discrepancy in the contributing factors. One based on crash times show similar crash times with the daily peak at the same hour. However, by taking into account population and population density, some patterns began to emerge.

Crashes in Upper Manhattan: UWS vs Rest of Upper Manhattan

Leading crash times

- Leading Crash Times in Upper West Side
- 16:00
 - 12:00
 - 11:00
- Leading Crash Times in Upper Manhattan
- 16:00
 - 17:00
 - 18:00

Population Distribution: UWS vs Rest of Upper Manhattan

Although it initially appeared that the Upper West Side had a higher rate of crashes than Upper Manhattan, a closer look shows that Upper Manhattan has the higher rate of car crashes. When broken down population-wise, the leading zip codes in crashes per 1000 people, are all located in Upper Manhattan.

This suggests that the discrepancy in the distribution of population and car crashes is caused by other factors that have not been measured in this data set.

A policy recommendation informed by this analysis will tackle the factors that make 16:00 or 4pm such a dangerous time on the roads regardless of location,
